

MEDIATORS OF INFLAMMATION

Dr. Eman Kreishan, M.D.

27/10/2025.

MEDIATORS OF INFLAMMATION

- ▶ The mediators of inflammation are the substances that initiate and regulate inflammatory reactions.
- ▶ The most important mediators of acute inflammation are:
 - vasoactive amine.
 - lipid products (prostaglandins and leukotrienes).
 - cytokines (including chemokines),
 - products of complement activation

General properties of the mediators of inflammation

- ❑ 1. Mediators may be produced locally by cells at the site of inflammation, or may be derived from circulating inactive precursors that are activated at the site of inflammation.
- Cell-derived mediators are rapidly released from intracellular granules or synthesized de novo in response to a stimulus
They are most important for reactions against offending agents in tissues.
- Plasma-derived mediators (e.g., complement proteins) are present in the circulation .
They are produced mainly in the liver, are effective against circulating microbes

- ▶ 2. Active mediators are produced only in response to various molecules that stimulate inflammation, including microbial products and substances released from necrotic cells.
- ▶ 3. Most of the mediators are short-lived.
- ▶ 4. One mediator can stimulate the release of other mediators.

Major groups.

- ▶ 1. Vasoactive Amines: Histamine and Serotonin.
- ▶ 2. Arachidonic Acid Metabolites.
- ▶ 3. Cytokines and Chemokines.
- ▶ 4. Complement System.

1. Vasoactive Amines: 1. Histamine

- ▶ Vasoactive means: act on blood vessels.
- ▶ They are stored as preformed molecules in cells and are therefore among the first mediators to be released during inflammation.
- ▶ Released from mast cells, which are normally present in the connective tissue adjacent to blood vessels.
- ▶ Histamine also is found in blood basophils and platelets

IgE Cross-linking Induces Mast Cell Activation and Degranulation

- ▶ It is stored in mast cell granules and is released by degranulation in response to a variety of stimuli, including :
 - ▶ (1) physical injury, such as trauma, cold, or heat, by unknown mechanisms.
 - ▶ (2) binding of antibodies to mast cells, which underlies immediate hypersensitivity (allergic) reactions.
 - ▶ (3) products of complement called anaphylatoxins (C3a and C5a).

❖ ACTION OF HISTAMINE:

- ▶ Its vasoactive effects are mediated mainly via binding to H1 receptors.
- ▶ Histamine actions:
 - Vasodilation.
 - increases vascular permeability of venules, producing interendothelial gaps in postcapillary venules.
 - contraction of some smooth muscles

- ▶ The antihistamine drugs that are commonly used to treat some inflammatory reactions, such as allergies, are H1 receptor antagonists that bind to and block the receptor.

2. Serotonin

- ▶ Serotonin (5-hydroxytryptamine) is a preformed vasoactive mediator present in platelets and certain neuroendocrine cells, such as in the gastrointestinal tract, and in mast cells in rodents but not humans.
- ▶ Its primary function is as a neurotransmitter in the gastrointestinal tract.
- ▶ It also is a vasoconstrictor, but the importance of this action in inflammation is unclear

2. Arachidonic Acid Metabolites

- ▶ The lipid mediators prostaglandins and leukotrienes are produced from arachidonic acid present in membrane phospholipids, and they stimulate vascular and cellular reactions in acute inflammation.
- ▶ Arachidonic acid is a 20-carbon polyunsaturated fatty acid that is derived from dietary sources or by conversion from the essential fatty acid linoleic acid.

Arachidonic Acid pathway

A. Prostaglandins.

- ▶ Prostaglandins (PGs) are produced by mast cells, macrophages, endothelial cells, and many other cell types.
- ▶ They are involved in the vascular and systemic reactions of inflammation.
- ▶ They are generated by the actions of two cyclooxygenases called COX-1 and COX-2.
- ▶ Prostaglandins are named based on structural features coded by a letter (e.g., PGD, PGE, PGF, PGG, and PGH) and a subscript numeral (e.g., 1, 2), which indicates the number of double bonds in the compound.

- ▶ The most important prostaglandins in inflammation are PGE₂, PGD₂, PGF_{2a}, PGI₂ (prostacyclin), and TXA₂ (thromboxane A₂).

Characteristics comparison between COX-1 and COX-2

	COX-1	COX-2
Synthesis	intrinsic	induced
Functions	physiological: gastrointestinal protection platelet aggregation regulation vascular resistance regulation renal blood flow regulation	physiological: production of PG elevated during pregnancy pathological: producing proteinase, PG, and other inflammatory mediators

Prostaglandins and systemic manifestations of inflammation.

- ▶ In addition to their local effects, prostaglandins are involved in the pathogenesis of:
 - ▶ pain and fever.
- ▶ PGE₂ makes the skin hypersensitive to painful stimuli, and causes fever during infections

2. Leukotrienes.

- ▶ Leukotrienes are produced in leukocytes and mast cells by the action of lipoxygenase and are involved in vascular and smooth muscle reactions and leukocyte recruitment.

❖ LTB₄:

- Produced by neutrophils and some macrophages.
- Potent chemotactic agent and activator of neutrophils, causing aggregation and adhesion of the cells to venular endothelium.
- Generation of ROS.
- Release of lysosomal enzymes.

❖ LTC₄ ,LTD₄ and LTE₄:

- Produced mainly in mast cells.
- Cause intense vasoconstriction, bronchospasm (important in asthma), and increased permeability of venules.

3. Lipoxins

- ▶ Are generated from arachidonic acid by the lipoxygenase pathway.
- ▶ Unlike prostaglandins and leukotrienes, the lipoxins suppress inflammation by inhibiting the recruitment of leukocytes.
- ▶ They inhibit neutrophil chemotaxis and adhesion to endothelium.

Pharmacologic Inhibitors of Prostaglandins and Leukotrienes

- ▶ The importance of eicosanoids in inflammation has driven attempts to develop drugs that inhibit their production or actions and thus suppress inflammation. These anti-inflammatory drugs include the following:

1. Cyclooxygenase inhibitors

- ▶ It include aspirin and other (NSAIDs), such as ibuprofen.
- ▶ They inhibit both COX-1 and COX-2 and thus block all prostaglandin synthesis (hence their efficacy in treating pain and fever).
- ▶ Selective COX-2 inhibitors:
 - ▶ are 200- to 300-fold more potent in blocking COX-2 than COX-1.
 - ▶ COX-1 is responsible for the production of prostaglandins that are involved in both inflammation and physiologic functions such as protecting gastric epithelial cells from acid-induced injury, whereas COX-2 generates prostaglandins that are involved only in inflammation.
 - ▶ So in patient with gastric ulceration?

But ????????????

- ▶ selective COX-2 inhibitors may increase the risk of cardiovascular and cerebrovascular events?
- ▶ possibly because they impair endothelial cell production of prostacyclin (PGI₂), which prevents thrombosis, while leaving intact the COX-1-mediated production by platelets of TXA₂, which induces platelet aggregation.
- ▶ Thus, selective COX-2 inhibition may tilt the balance toward vascular thrombosis

▶ 2. Lipoxygenase inhibitors:

- Pharmacologic agents that inhibit leukotriene production (e.g., zileuton) are useful in the treatment of asthma.

▪

▪ 3. Corticosteroids:

- are broad-spectrum anti-inflammatory agents that :
- reduce the transcription of genes encoding COX-2, phospholipase A2, proinflammatory cytokines (e.g., IL-1 and TNF), and iNOS.

▪ 4. Leukotriene receptor antagonists:

- It block leukotriene receptors and prevent the actions of the leukotrienes.
- These drugs (e.g., Montelukast) are useful in the treatment of asthma.

3. Cytokines and Chemokines

▶ Cytokines:

- ▶ are proteins secreted by many cell types (principally activated lymphocytes, macrophages, and dendritic cells, but also endothelial, epithelial, and connective tissue cells) that mediate and regulate immune and inflammatory reactions.

▶ A. Tumor Necrosis Factor and Interleukin-1:

- ▶ Serve critical roles in leukocyte recruitment by promoting adhesion of leukocytes to endothelium and their migration through vessels.
- ▶ Produced by activated macrophages and dendritic cells under the effect of . Microbial products, foreign bodies, necrotic cells.
- ▶ The most important roles of these cytokines in inflammation are the following:
 - ▶ 1. Endothelial activation.
 - ▶ 2. Activation of leukocytes and other cells.
 - ▶ 3. Systemic acute-phase response.
 - ▶ 4. TNF regulates energy balance by promoting lipid and protein catabolism and by suppressing appetite.

- 
- ▶ TNF antagonists have been remarkably effective in the treatment of chronic inflammatory diseases:
 - ▶ rheumatoid arthritis.
 - ▶ psoriasis.
 - ▶ some types of inflammatory bowel disease.

- Sustained production of TNF contributes to cachexia, a pathologic state characterized by weight loss, muscle atrophy, and anorexia that accompanies some chronic infections and cancers

Fig. 3.10 Major roles of cytokines in acute inflammation. PDGF, Platelet-derived growth factor; PGE, prostaglandin E; PGI, prostaglandin I.

▶ B. Chemokines:

- ▶ Chemokines are a family of small proteins that act primarily as chemoattractants for specific types of leukocytes.
- ▶ Chemokines mediate their activities by binding to seven-transmembrane G protein-coupled receptors.
- ▶ They are classified into four major groups, according to the arrangement of cysteine (C) residues in the proteins:
 - ▶ 1. C-X-C chemokines :
 - ▶ have one amino acid residue separating the first two of the four conserved cysteines.
 - ▶ These chemokines act primarily as neutrophils chemoattractant. IL-8 (now called CXCL8) is typical of this group.

- ▶ 2. C-C chemokines:
- ▶ have the first two conserved cysteine residues adjacent.
- ▶ include monocyte chemoattractant protein (MCP-1, CCL2), eotaxin (CCL11), and macrophage inflammatory protein-1 α (MIP-1 α , CCL3).
- ▶ mainly serve as chemoattractants for monocytes, eosinophils, basophils, and lymphocytes.

- ▶ 3. C chemokines :
 - ▶ lack the first and third of the four conserved cysteines.
 - ▶ The C chemokines (e.g., lymphotactin, XCL1) are relatively specific for lymphocytes.
- ▶ 4. CX3C chemokines :
 - ▶ contain three amino acids between the first two cysteines
 - ▶ The only known member of this class is called fractalkine (CX3CL1).

4. Complement System

- ▶ The complement system is a collection of soluble proteins and their membrane receptors that function mainly in host defense against microbes and in pathologic inflammatory reactions.
- ▶ There are more than 20 complement proteins, some of which are numbered C1 through C9.
- ▶ In the process of complement activation, several cleavage products of complement proteins are elaborated that cause increased vascular permeability, chemotaxis, and opsonization

▶ The critical step in complement activation is the proteolysis of the third (and most abundant) component, C3. Cleavage of C3 can occur by one of three pathways:

▶ 1. The classical pathway:

▶ which is triggered by fixation of C1 to antibody (IgM or IgG) that has combined with antigen .

▶ 2. The alternative pathway:

▶ which can be triggered by microbial surface molecules (e.g., endotoxin), complex polysaccharides, and other substances, in the absence of antibody.

▶ 3. The lectin pathway:

▶ in which plasma mannose-binding lectin binds to carbohydrates on microbes and directly activates C1.

- ▶ All three pathways of complement activation lead to the formation of an enzyme called the C3 convertase, which splits C3 into two functionally distinct fragments, C3a and C3b.
- ▶ C3a is released, and C3b becomes covalently attached to the cell or molecule where the complement is being activated.
- ▶ More C3b then binds to the previously generated fragments to form C5 convertase, which cleaves C5 to release C5a and leave C5b attached to the cell surface.
- ▶ C5b binds the late components (C6-C9), culminating in the formation of the membrane attack complex (MAC, composed of multiple C9 molecules).

❖ Complement proteins are present in inactive forms in the plasma, and many of them are activated to become proteolytic enzymes that degrade other complement proteins.

The complement system has three main functions:

- ▶ 1. Inflammation.:
- ▶ C5a, C4a and C3a are called anaphylatoxins.
- ▶ They stimulate histamine release from mast cells and thereby increase vascular permeability and cause vasodilation.
- ▶ C5a also is:
 - a chemotactic agent for neutrophils, monocytes, eosinophils, and basophils.
 - activates the lipoxygenase pathway of arachidonic acid metabolism in neutrophils and monocytes, causing release of more inflammatory mediators.

▶ 2. Opsonization and phagocytosis:

- ▶ C3b and its cleavage product iC3b (inactive C3b act as opsonins).
- ▶ promote phagocytosis by neutrophils and macrophages, which bear cell surface receptors for these complement fragments.

▶ 3. Cell lysis:

- ▶ The deposition of the MAC on cells drills holes in the cell membrane, making the cells permeable to water and ions and resulting in their osmotic death (lysis).
- ▶ This function of complement is important mainly for the killing of microbes with thin cell walls, such as Neisseria bacteria.
