

# Anti-Parkinson Drugs

Prof. Saed M Al-dalaen  
Mutah University  
Jordan 2025

# Anti-Parkinson Drugs

## Pathogenesis:

- Imbalance between cholinergic & dopaminergic neurotransmission
- Degeneration of nigrostriated dopaminergic neurons, substantia nigra & corpus pallidum that control & coordinate motor activity

↓  
Produce dopamine  
For movement, Cognition

From tyrosin  
[Natural Amino Acid]  
Tertiary

(lev)  
**L-dopa**

crosses brain barrier  
and converts to

**dopamine**

stimulates

**D2 receptors**

inhibits

**adenylyl cyclase**

reduces

reduces

closes

[No release]  
**Ca<sup>2+</sup> channel**

closes

**IP3**

**cyclic AMP**

decreases

**intracellular Ca<sup>2+</sup>**

inhibits

**firing of striatal cholinergic nerves**

restores balance

treats

**Parkinson's Disease**

→ normal Ach but will be dominant.

**reduced dopamine in Parkinson's**

**cholinergic overactivity**

**substantia nigra dopamine**

**corpus striatum cholinergic**

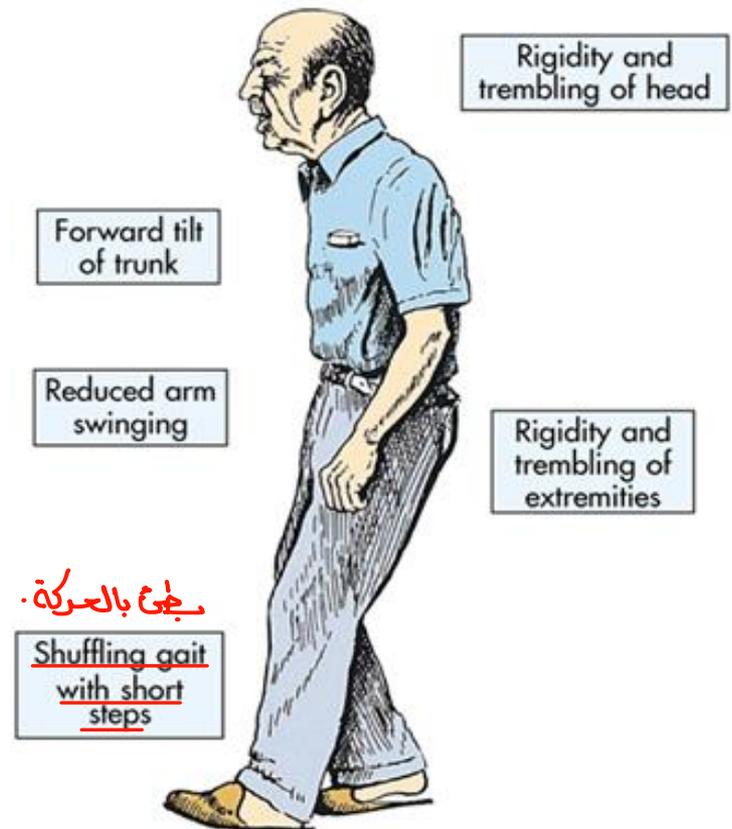

العلاج دة يكون Temporal

# Manifestations

- Involuntary movements
- Rigidity [↑Ca<sup>+</sup>]
- Tremor
- Bradykinesia
- Postural instability
- Dementia الخرف

بطيء بالحركة.

الحناء

بطيء بالحركة.

# Causes

- Unclear
- A number of factors may have a role:
  - Environmental – toxins
  - Free Radicals – there is a increase in post-mortem brain sections
  - Aging – age related decline in dopamine production
  - Genetic – possible, no single gene identified
  - Traumatic (e.g. in boxers).

↑ degenerative neurons.

Aging – age related decline in dopamine production

– Genetic – possible, no single gene identified

– Traumatic (e.g. in boxers).

↳ repeated head of injury

some AE of Drugs:

→ psychosis

# The Drugs

It is palliative not curative & includes:

❑ **Dopaminergic drugs (improving dopamine functioning):**

- 1) ● **Levodopa** (Dopamine precursor)
- 2) ● **Bromocriptine** (Dopamine receptor agonists)  
[D<sub>2</sub>] → D<sub>1</sub> → involuntary movement  
→ D<sub>2</sub> → sign and symptoms of Parkinson.
- 3) ● **Amantadine** (Increase synthesis & release)  
→ + reduce reuptake
- 4) ● Selective monoamine oxidase B inhibitors
- 5) ● Catechol-O-methyltransferase inhibitors

❑ **Antimuscarinic drugs** → AE: Dry mouth [xerostoma]

- ❑ useful in mild cases & in drug-induced parkinsonism (by phenothiazines)

❑ **Drug combination**

# Drug therapy.....cont

↑ Flexibility

- Dopaminergic drugs improve bradykinesia & rigidity
- Anti-cholinergic agents improves rigidity & tremor

Bradykinesia      ما لها علاقة بال  
dementia      ولا

# Levodopa

- Dopamine is ineffective because it is metabolized enzymatically in GIT & liver & does not cross BBB
- L-dopa is a natural AA precursor of dopamine & crosses actively BBB [ Aim of treatment ✓ ]
- Converted by remaining neuron (20%) into dopamine

# Levodopa

- Peripheral decarboxylation of L-dopa occurs and produces peripheral adverse effects as nausea, vomiting & hypotension
  - So, peripheral decarboxylation of L-dopa should be prevented to reduce these peripheral adverse effects
- decarboxylas inhibitor enzyme :*
- Carbidopa and benserazide are examples

# Preparations

- Levodopa + carbidopa → Sinemet
- Levodopa + benserazide →  
Co-beneldopa
- Decarboxylase inhibitors do not cross BBB  
so decreases levodopa dose

# Pharmacokinetics

- Absorbed by the small intestine by an active transport system [ Amino Acid ]
- Good GI absorption on empty stomach [ in the morning ]
- High protein diet impairs absorption
- t 1/2 1-2 hours

Both compete for the same pathway!  
BB:B and Stomach

# Adverse effects

## □ Peripheral

*nausea vomiting*

- N, V (prevented by cyclizine)

- Postural hypotension

- **Arrhythmias**

*↳ due to potent vasoconstriction.*

*(1<sup>st</sup> gen Antihistamine drug)*

# Adverse effects

## □ Central:

### ● Involuntary movements [D<sub>1</sub>]

- dyskinesia, restlessness, choreo-athetosis ↗ Abnormal skeletal movement.

### ● Mental changes:

- Hallucination, confusion & agitation like psychosis (due to increased dopamine levels in the cortex and limbic system).

# Adverse effects

- End-of dose deterioration
  - Due to rapid disappearance of dose effects.
  - corrected by small frequent doses [2,2,2] مثلا : كل ساعتين
- On-off phenomenon:
  - ON phase at the start of treatment (good control of Parkinson symptoms but dyskinesia & agitation are obvious) (Alternative)
  - OFF phase: severe Parkinson features due to sudden disappearance of dose effect
  - corrected by apomorphine. → Non-narcotic cholinergic

# Drug interactions with L-dopa

ex: Phenzine ← [Anti depressant]

- Nonselective MAOI+ levodopa .....  
Hypertensive crisis (↑ NE)
- Pyridoxine (B6) + levodopa .....  
Attenuation of effects due to increased peripheral metabolism (not in the presence of decarbo inhibitors)
- Levodopa is used cautiously in; glaucoma, heart disease (arrhythmias) & psychosis

# Amantadine (dopamine release)

- is an anti-virus agent against influenza, used as adjuvant therapy for dyskinesia effects
- Increases synthesis and release of dopamine & decreases reuptake
- it also has slight antimuscarinic effects

# Amantadine (dopamine release)

- improves bradykinesia & rigidity
- effects are < Levodopa > anti-muscarinics effects

*levo > Amantadine > Antimuscarinic*

# Pharmacokinetics

- Well absorbed
- It has long 1/2 life
- Execrated unchanged by the kidney

# Bromocriptine (parlodel)

- is an ergot alkaloid [Natural]
- acts as a dopamine agonist on D2 receptors  
also a weak  $\alpha$ -adrenoreceptor antagonist [v.o.]  
(إنتا مينيلا مع levo)
- used mainly with levodopa
- start at low dose then increased gradually weekly (2-3 months)

# Bromocriptine (parlodel)

- oral, rapid absorption
- $t_{1/2}$  5 hours
- useful in patients with End-of dose deterioration with levodopa (to overcome the rapid disappearance of L-Dopa effects)

# Adverse effects

- N, V, *in high doses :*
- Postural hypotension (alpha blocking)
- Confusion
- Hallucination
- Insomnia

# Selegiline (Deprenyl)

- is a selective, irreversible MAO B inhibitor; increase dopamine in brain tissues
- increases effects of levodopa & decreases its dose
- useful in End-of dose deterioration with levodopa

# Selegiline (Deprenyl)

- Early stage-prescribed on its own to delay need for Levodopa and there is good evidence for its slowing down of PD [Parkinson disease] progression (protect neurons)

# Adverse effects

- Nausea, vomiting constipation, dry mouth
- insomnia & increases ABP with high doses
- does not produce cheese-drug interaction (tyramine is metabolized by MAO A)

B.P↑

# Apomorphine

- is a derivative of morphine
- acts as an agonist at D1 & D2 receptors
- useful in Parkinson's disease with On-OFF phenomenon
- given sc or IV infusion
- may cause N, V & respiratory depression
- rapid onset with a short duration of action

*due to* agonist at D1 & D2 receptors  
↗

# Adverse effects

- N and V
- Dyskinesia (D1 effect)
- Hallucinations
- Respiratory depression
- Peripheral vasospasm (Raynaunds)

↓  
due to potent V.C

# Central Anti-muscarinics

- **Benzhexol, Orphenadrine, Benztropine, Procyclidine**
- Cross well BBB
- They improve tremor, rigidity & sialorrhoea (not bradykinesia), *not dyskinesia*
- Useful in mild case
- Oral and IM or IV in acute drug-induced dystonia reactions or parkinsonism.

# Drugs to avoid

Generic Name	Prescribed for
Prochlorperazine	N +V, Dizziness
Prephenazine	Depression
Flupentixol	Confusion, Hallucinations
Chlorpromazine	“
Pimozide	“
Sulpiride	“
